Time series is a sequence of data points in chronological sequence, most often gathered in regular intervals. Time series analysis can be applied to any variable that changes over time and generally speaking, usually data points that are closer together are more similar than those further apart. Time series can be defined as a sequence of a metric is recorded over regular time intervals. Depending on the frequency, a time series can be of yearly, quarterly, monthly etc. There are 2 things which Time-series make different from the regular regression problem. First one is Time-dependent.

The Signature of a time series is a universal description for a stream of data derived from the theory of controlled differential equations. Over the last years, this technique has been used successfully applied in a wide array of Machine Learning tasks dealing with sequential data, such as the chinese character recognition problem or extracting information from the signature of a financial data stream.

Introduction to Time Series Analysis. Time series methods take into account possible internal structure in the data. Time series data often arise when monitoring industrial processes or tracking corporate business metrics. The essential difference between modeling data via time series methods or using the process monitoring methods discussed earlier in this chapter is the following:

Time series analysis refers to problems in which observations are collected at regular time intervals and there are correlations among successive observations. Applications cover virtually all areas of Statistics but some of the most important include economic and financial time series, and many areas of environmental or ecological data.

The idea of fractional differencing is introduced in terms of the infinite filter that corresponds to the expansion of  $(1 - B)^{-d}$ . When the filter is applied to white noise, a class of time series is generated with distinctive properties, particularly in the very low frequencies and provides potentially useful long-memory forecasting properties.

The author also introduces and explains techniques that are widely used in applied work, although rarely introduced in detail in non-specialist texts. These include integrated time series, cointegration, simulation analysis, Johansen's approach to multivariate cointegration and ARCH. The text also illustrates the central distinction between stationary and non-stationary time series, which is of crucial importance in many areas of analysis, especially in macroeconomics and financial economics.
